## 5.17

Robust linear programming with polyhedral uncertainty. Consider the robust LP:

minimize 
$$c^T x$$
 subject to 
$$\sup_{a \in P_i} a^T x \leq b_i, \ i = 1, ..., m$$

with variable  $x \in R^n$ , where  $P_i = \{a: C_i a \leq d_i\}$ . The problem data are  $a \in R^n$ ,  $C_i \in R^{m_i \times n}$ ,  $d_i \in R^{m_i}$ , and  $b \in R^m$ . We assume the polyhedra  $P_i$  are nonempty. Show that this problem is equivalent to the LP:

minimize 
$$c^T x$$
 subject to 
$$d_i^T z_i \leq b_i, \ i=1,...,m$$
 
$$C_i z_i = x, \ i=1,...,m$$
 
$$z_i \succeq 0, \ i=1,...,m$$

with variables  $x \in \mathbb{R}^n$ ,  $z_i \in \mathbb{R}^{m_i}$ , i = 1, ..., m. Hint: find the dual of the problem of maximizing  $a_i^T x$  over  $a_i \in P_i$  (with variable  $a_i$ ).

Solution:

The problem of maximizing  $a_i^T x$  over  $a_i \in P_i$  (with variable  $a_i$ ) is:

maximize 
$$a_i^T x$$
  
subject to  $a_i \in P_i$ , where  $P_i = \{a: C_i a \leq d_i\}$ 

or

minimize 
$$-a_i^T x$$
  
subject to 
$$C_i a_i \leq d_i$$

The Lagrange dual of this problem is:

minimize 
$$\sum_{i=1}^m \lambda_i d_i$$
 subject to 
$$C_i \lambda_i = x$$
 
$$\lambda_i \succeq 0$$

The optimal value of this problem is less or equal to  $b_i$ , so we have the equivalent problem to our LP:

minimize 
$$c^T x$$
 subject to 
$$d_i^T \lambda_i \leq b_i, \ i=1,...,m$$
 
$$C_i \lambda_i = x, \ i=1,...,m$$
 
$$\lambda_i \succeq 0, \ i=1,...,m$$

## **5.40**

 $\rm E$  - optimal experiment design. A variation on two optimal experiment design problems of exercise 5.10 is the  $\rm E$  - optimal design problem:

minimize 
$$\lambda_{max}(\sum_{i=1}^p x_i v_i v_i^T)^{-1}$$
 subject to 
$$x \succeq 0, \ \mathbf{1}^T x = 1$$

(See also §7.5.) Derive a dual for this problem first by reformulating it as:

minimize 
$$1/t$$
 subject to 
$$\sum_{i=1}^{p} x_i v_i v_i^T \succeq t \boldsymbol{I}$$
 
$$x \succeq 0, \ \boldsymbol{1}^T x = 1$$

with variables  $t \in R$ ,  $x \in R^p$  and domain  $R_{++} \times R^p$ , and applying Lagrange duality. Simplify the dual problem as much as you can.

Solution: Let us introduce a variable  $t \in R_{++}$ . Then for a matrix A, inequality  $\lambda_{max}(A^{-1}) \leq 1/t$  means  $A^{-1} \leq \frac{1}{t}I$ , or  $A \leq tI$ . Setting A to  $\sum_{i=1}^p x_i v_i v_i^T$  we get a problem:

minimize 
$$1/t$$
 subject to 
$$\sum_{i=1}^{p} x_i v_i v_i^T \succeq t \boldsymbol{I}$$
 
$$x \succeq 0, \ \boldsymbol{1}^T x = 1$$

The Lagrangian is:

$$L(x, t, Z, z) = 1/t - tr(Z(\sum_{i=1}^{p} x_i v_i v_i^T - t \mathbf{I})) - z^T x + \nu(\mathbf{1}^T x - 1) = 1/t + t tr(Z) + \sum_{i=1}^{p} x_i (-v_i^T Z v_i - z_i + \nu) - \nu$$

the infimum of x is bounded below only if  $-v_i^T Z v_i - z_i + \nu = 0$ . The

$$inf_{\nu}1/t + t \operatorname{tr}(Z) = \begin{cases} 2\sqrt{\operatorname{tr}(Z)}, & Z \succeq 0\\ -\infty, & \text{otherwise} \end{cases}$$

the dual function is

$$L(Z, z, \nu) = \begin{cases} 2\sqrt{tr(Z)} - \nu, & Z \succeq 0, \ -v_i^T Z v_i - z_i + \nu = 0, \\ -\infty, & \text{otherwise} \end{cases}$$

The dual problem:

maximize 
$$2\sqrt{tr(Z)} - \nu$$
 subject to 
$$v_i^T Z v_i + z_i \leq 0, \ i=1,...,p$$
 
$$Z \succeq 0, \ \nu \geq 0$$

We can define  $W = (1/\nu)Z$ 

maximize 
$$2\sqrt{\nu}\sqrt{tr(W)} - \nu$$
 subject to 
$$v_i^T W v_i \leq 1, \ i = 1,...,p$$
 
$$W \succeq 0, \ \nu \geq 0$$

Maximizing over  $\nu$  we get  $\nu = tr(W)$ , so the problem is:

maximize 
$$tr(W)$$
 subject to 
$$v_i^T W v_i \leq 1, \ i=1,...,p$$
 
$$W \succ 0$$

### 6.3

Formulate the following approximation problems as LPs, QPs, SOCPs, or SDPs. The problem data are  $A \in \mathbb{R}^{n \times m}$  and  $b \in \mathbb{R}^m$ . The rows of A are denoted  $a_i^T$ .

(a) Deadzone-linear penalty approximation: minimize  $\sum_{i=1}^{m} \phi(a_i^T x - b_i)$ , where

$$\phi(u) = \begin{cases} 0, & |u| \le a \\ |u| - a, & |u| > a \end{cases}$$

where a > 0.

(b) Log-barrier penalty approximation: minimize  $\sum_{i=1}^{m} \phi(a_i^T x - b_i)$ , where

$$\phi(u) = \begin{cases} -a^2 log(1 - (u/a)^2), & |u| < a \\ \infty, & |u| \ge a \end{cases}$$

with a > 0.

(c) Huber penalty approximation: minimize  $\sum_{i=1}^{m} \phi(a_i^T x - b_i)$ , where

$$\phi(u) = \begin{cases} u^2, & |u| \le M \\ M(2|u| - M), & |u| > M \end{cases}$$

with M > 0.

(d) Log-Chebyshev approximation: minimize  $\max_{i=1,\dots,m} |log(a_i^T x) - log(b_i)|$ . We assume  $b \succ 0$ . An equivalent convex from is

minimize 
$$t$$
 subject to 
$$1/t \le a_i^T x/b_i \le t, \ i=1,...,m$$

with variables  $x \in \mathbb{R}^n$  and  $t \in \mathbb{R}$  and domain  $\mathbb{R}^n \times \mathbb{R}_{++}$ .

(e) Minimizing the sum of the largest k residuals:

minimize 
$$\sum_{i=1}^{k} |r|_{[i]}$$
 subject to 
$$r = Ax - b$$

where  $|r|_{[1]} \geq |r|_{[2]} \geq,..., \geq |r|_{[m]}$  are the numbers  $|r_1|, |r_2|,..., |r_m|$  sorted in decreasing order. (For k=1 this reduces to  $l_{\infty}$  - norm approximation; for k=m this reduces to  $l_1$  norm approximation.) Hint: See exercise 5.19.

Solution:

(a) Introduce the variable  $y \in R^m$  so that  $|a_i^T x - b_i| \le |a + y_i|, y_i \ge 0$  then we have equivalent problem:

minimize 
$$\mathbf{1}^T y$$
 subject to 
$$-y-a\mathbf{1} \preceq Ax-b \preceq y+a\mathbf{1}$$
 
$$y \succeq 0$$

(b)

Introduce the variable y = Ax - b,  $t_i \le (1 - y_i/a)(1 + y_i + a)$ , and add inequality  $-a \le y_i \le a$  this problem will transform to:

maximize 
$$\prod_{i=1}^m t_i^2$$
 subject to 
$$y=Ax-b$$
 
$$t_i \leq (1-y_i/a)(1+y_i/a), \ i=1,...,m$$
 
$$-1 \leq y_i/a \leq 1, \ i=1,...,m$$

with variables  $t, y \in \mathbb{R}^m$ ,  $x \in \mathbb{R}^n$ . Next assume that  $m = 2^k$ . It can be done without loss of generality, as in other case we always can add missing components of  $y_i$  as unity values  $(a_i = 0 \text{ and } b_i = -1)$ . Lets transform this problem for m = 4.

maximize 
$$(t_1t_2t_3t_4)^2$$
 subject to 
$$y = Ax - b$$
 
$$t_i \leq (1 - y_i/a)(1 + y_i/a), \ i = 1, ..., m$$
 
$$-1 \leq y_i/a \leq 1, \ i = 1, ..., m$$

this problem is equivalent to:

maximize 
$$z_1z_2$$
 subject to 
$$z_1^2 \leq t_1t_2$$
 
$$z_2^2 \leq t_3t_4$$
 
$$y = Ax - b$$
 
$$t_i \leq (1-y_i/a)(1+y_i/a), \ i=1,...,m$$
 
$$-1 \leq y_i/a \leq 1, \ i=1,...,m$$

and also as:

maximize 
$$z$$
 subject to 
$$z^2 \leq z_1 z_2$$
 
$$z_1^2 \leq t_1 t_2$$
 
$$z_2^2 \leq t_3 t_4$$
 
$$y = Ax - b$$
 
$$t_i \leq (1 - y_i/a)(1 + y_i/a), \ i = 1, ..., m$$
 
$$-1 \leq y_i/a \leq 1, \ i = 1, ..., m$$

as it is easy to show that  $x^Tx \leq yz$  where  $x \in R^n, y, z \in R_+$  is equivalent to:

$$\left\| \begin{bmatrix} x \\ y - z \end{bmatrix} \right\|_2 \le y + z$$

overriding the first three inequalities with their norm analogue we have:

minimize 
$$-z$$
subject to 
$$\left\| \begin{bmatrix} z \\ z_1 - z_2 \end{bmatrix} \right\|_2 \le z_1 + z_2$$

$$\left\| \begin{bmatrix} z_1 \\ t_1 - t_2 \end{bmatrix} \right\|_2 \le t_1 + t_2$$

$$\left\| \begin{bmatrix} z_2 \\ t_3 - t_4 \end{bmatrix} \right\|_2 \le t_3 + t_4$$

$$y = Ax - b$$

$$t_i \le (1 - y_i/a)(1 + y_i/a), \ i = 1, \dots, m$$

$$-1 \le y_i/a \le 1, \ i = 1, \dots, m$$

which is Second Order Cone Program (SOCP).

(c) Lets show that this problem is equivalent to QP:

minimize 
$$\sum_{i=1}^{m} (u_i^2 + 2Mv_i)$$
 subject to 
$$-u - v \preceq Ax - b \preceq u + v$$
 
$$0 \preceq u \preceq M\mathbf{1}$$
 
$$v \succeq 0$$

Proof: Lets fix x in our QP. For the optimum point we must have  $u_i + v_i = |a_i^T x - b_i|$ . In other case, if  $u_i + v_i > |a_i^T x b_i|$  and  $0 \le u_i \le M$  and  $v_i \ge 0$ , then as  $u_i$  and  $v_i$  are not both zero, we can decrease  $u_i$  and/or  $v_i$  without violating the constraints and the objective will be decreased also. So, at the optimum we have:

$$v_i = |a_i^T x - b_i| - u_i$$

Eliminating  $v_i$  yields equivalent problem:

minimize 
$$\sum_{i=1}^{m} (u_i^2 - 2Mu_i + 2M|a_i^T x - b_i|)$$
 subject to 
$$0 \leq u_i \leq \min(M, |a_i^T x - b_i|)$$

It  $M > |a_i^T x - b_i|$  the optimal choice for  $u_i$  is  $|a_i^T x - b_i|$ . In this case the objective function reduces to  $|a_i^T x - b_i|^2$ . Otherwise the optimal choice for  $u_i$  is M, and the objective function reduces to  $2M|a_i^T x - b_i| - M^2$ . So, we conclude that with

 $\phi(a_i^Tx-b_i)$  these problems are equivalent. (c) The constraint  $ta_i^Tx\geq b_i,\ t\geq 0,\ a_i^Tx\geq 0$  can be formulated as an LMI

$$\begin{bmatrix} t & \sqrt{b_i} \\ \sqrt{b_i} & a_i^T x \end{bmatrix} \succeq 0$$

or as follows:

$$\left\| \begin{bmatrix} 2\sqrt{b_i} \\ t - a_i^T x \end{bmatrix} \right\|_2 \le t + a_i^T x$$

(e) As in exercise 5.19, we have a problem:

minimize 
$$kt + \mathbf{1}z$$
 subject to 
$$-t\mathbf{1} - z \preceq Ax - b \preceq t\mathbf{1} + z$$
 
$$z \succeq 0$$

where  $x \in \mathbb{R}^n$ ,  $t \in \mathbb{R}$ ,  $z \in \mathbb{R}^m$ 

#### 6.8 a - b

Formulate the following robust approximation problems as LPs, QPs, SOCPs, or SDPs. For each subproblem, consider the  $l_1$ -,  $l_2$ -, and the  $l_{\infty}$ - norms.

(a) Stochastic robust approximation with a finite set of parameter values, i.e., the sum of - norms problem

minimize 
$$\sum_{i=1}^{k} p_i \|A_i x - b\|$$

where  $p \succeq 0$  and  $\mathbf{1}^T p = 1$ . (See §6.4.1.)

(b) Worst-case robust approximation with coefficient bounds:

$$\sup_{A\in\mathcal{A}}\|Ax-b\|$$

where  $\mathcal{A} = \{A \in \mathbb{R}^{m \times n} | l_{ij} \leq a_{ij} \leq u_{ij}, i = 1, ..., m, j = 1, ..., n\}$ . Here the uncertainty set is described by giving upper and lower bounds for the components of A. We assume  $l_{ij} < u_{ij}$ .

Solution:

(a)  $l_1$  norm: Introduce a slack variable  $y:|y_i| \succeq |A_ix - b|$ . We have LP:

minimize 
$$p^T y$$
  
subject to  $-y_i \leq A_i x - b \leq y_i$ 

 $l_2$  norm: Introduce a slack variable  $y: y_i \succeq ||A_i x - b||_2$ . We have SOCP:

minimize 
$$p^T y$$
 subject to  $||A_i x - b|| \leq y_i$ 

 $l_{\infty}$  norm: We have LP:

minimize 
$$p^T y$$
  
subject to  $-y_i \mathbf{1} \leq A_i x - b \leq y_i \mathbf{1}$ 

(b) 
$$\sup_{l_{ij} \le a_{ij} \le u_{ij}} |a_i^T x - b_i| = \sup_{l_{ij} \le a_{ij} \le u_{ij}} \max(-a_i^T x + b_i, a_i^T x - b_i) = \max(\sup_{l_{ij} \le a_{ij} \le u_{ij}} -a_i^T x + b_i, \sup_{l_{ij} \le a_{ij} \le u_{ij}} a_i^T x - b_i)$$

$$\sup_{l_{ij} \le a_{ij} \le u_{ij}} -a_i^T x + b_i = -a_i^T x + b_i + v_i^T |x|$$

where  $\bar{a}_{ij} = (u_{ij} + l_{ij})/2$ ,  $v_{ij} = (u_{ij} - l_{ij})/2$  and

$$\sup_{l_{ij} \le a_{ij} \le u_{ij}} a_i^T x - b_i = \overline{a}_i^T x - b_i + v_i^T |x|$$

Therefore

$$\sup_{l_{ij} \le a_{ij} \le u_{ij}} |a_i^T x - b_i| = |\bar{a}_i^T x - b_i| + v_i^T |x|$$

(a)  $l_1$  norm.

minimize 
$$\sum_{i=1}^{m} (|\overline{a}_i x - b_i| + v_i^T |x|)$$

Introducing slack variables  $y:|y_i|\geq |\overline{a}_ix-b_i|$  and  $w:|w_i|\geq |x_i|$  we have LP:

minimize 
$$\mathbf{1}^T(y+Vw)$$
 subject to 
$$-y\preceq \overline{A}x-b\preceq y\\ -w\preceq x\preceq w$$

 $l_2$  norm.

minimize 
$$\sum_{i=1}^{m} (|\overline{a}_i x - b_i| + v_i^T |x|)^2$$

introduce the same slack variables and variable y,w and the new variable t :  $t \leq ||y+Vw||_2$  we have SOCP:

minimize 
$$t$$
 subject to 
$$-y \preceq \overline{A}x - b \preceq y$$
 
$$-w \preceq x \preceq w$$
 
$$t \geq ||y + Vw||_2$$

 $l_{\infty}$  norm:

minimize 
$$\max_{i=1,\dots,m} (|\overline{a}_i x - b_i| + v_i^T |x|)^2$$

this can be expressed as LP:

minimize 
$$t$$
 subject to 
$$-y \preceq \overline{A}x - b \preceq y$$
 
$$-w \preceq x \preceq w$$
 
$$-t\mathbf{1} \preceq y + Vw \preceq t\mathbf{1}$$

## **A5.4**

Penalty function approximation. We consider the approximation problem

minimize 
$$\phi(Ax+b)$$

where  $a \in R^m \times n$ ,  $b \ inR^m$ , the variable is  $x \in R^n$ , and  $\phi : R^m \to R$  is a convex penalty function that measures the quality of the approximation  $Ax \approx b$ . We will consider the following choices of penalty function:

(a) Euclidean norm.

$$\phi(y) = ||y||_2 = (\sum_{k=1}^{m} y_k^2)^{1/2}$$

(b)  $l_1$  - norm:

$$\phi(y) = ||y||_1 = \sum_{k=1}^{m} |y_k|$$

(c) Sum of the largest m/2 absolute values:

$$\phi(y) = \sum_{k=1}^{m/2} |y_{[k]}|$$

where  $y_{[1]}, y_{[2]}, \dots$  denote the absolute values of the components of y sorted in the decreasing order.

(d) A piecewise-linear penalty.

$$\phi(y) = \sum_{k=1}^{m} h(y_k), \quad h(u) = \begin{cases} 0, & |u| \le 0.2\\ |u| - 0.2, & 0.2 \le |u| \le 0.3\\ 2|u| - 0.5, & |u| \ge 0.3 \end{cases}$$

(e) Huber penalty.

$$\phi(y) = \sum_{k=1}^{m} h(y_k), \quad h(u) = \begin{cases} u^2, & |u| \le M \\ M(2|u| - M), & |u| \ge M \end{cases}$$

with M = 0.2

(f) Log-barrier penalty.

$$\phi(y) = \sum_{k=1}^{m} h(y_k), \quad h(u) = -\log(1 - u^2), \quad dom \ h = \{u \mid |u| < 1.\}$$

with M = 0.2

Here is the problem. Generate data A and b as follows:

```
m = 200;
n = 100;
A = randn(m,n);
b = randn(m,1);
b = b/(1.01*max(abs(b)));
```

(The normalization of b ensures that the domain of  $\phi(Ax-b)$  is nonempty if we use the log-barrier penalty.) To compare the results, plot a histogram of the vector of residuals y=Ax-b for each of the solutions x, using the Matlab command

#### hist(A\*x-b,m/2);

Some additional hints and remarks for the individual problems:

- (a) This problem can be solved using least-squares  $(x=A\b)$ .
- (b) Use the CVX function norm(y,1).
- (c) Use the CVX function norm\_largest().
- (d) Use CVX, with the overloaded max(), abs(), and sum() functions.
- (e) Use the CVX function huber().
- (f) The current version of CVX handles the logarithm using an iterative procedure, which is slow and not entirely reliable. However, you can reformulate this problem as

maximize 
$$\prod_{k=1}^{m} ((1 - (Ax - b)_k)(1 + (Ax - b)_k)))^{1/2m},$$

and use the CVX function geo\_mean().

```
Solution:
    (a)
Matlab code:

m = 200;
n = 100;
A = randn(m,n);
b = randn(m,1);
b = b/(1.01*max(abs(b)));

## A12.6

Antenna array weight design. We consider an array of n omnidirectional antennas in a plane, at positions  $(x_k,y_k,)$  k=1,...,n. A unit plane wave with frequency  $\omega$  is incident from an angle  $\theta$ . This incident wave induces in the kth antenna element a (complex) signal  $exp(i(x_kcos(\theta)+y_ksin(\theta)-\omega t))$  (For simplicity we assume that the spatial units are normalized so that the wave number is one, i.e., the wavelength is  $\lambda=2\pi$ .) The baseband signals of the n antennas are combined linearly to form the output of the antenna array

$$G(\theta) = \sum_{k=1}^{n} \omega_k e^{x_k \cos(\theta) + y_k \sin(\theta)}$$

$$= \sum_{k=1}^{n} (\omega_{re,k} \cos(\gamma_k(\theta)) - \omega_{im,k} \sin(\gamma_k(\theta)) + (\omega_{re,k} \sin(\gamma_k(\theta)) + \omega_{im,k} \cos(\gamma_k(\theta)))$$

if we define  $\gamma_k(\theta) = x_k cos(\theta) + y_k sin(\theta)$  The complex weights in the linear combination,  $\omega_k = \omega_{re,k} + i\omega_{im,k}$  are called the antenna array coefficients or shading coefficients, and will be the design variables in the problem. For a given set of weights, the combined output  $G(\theta)$  is a function of the angle of

arrival  $\theta$ . of the plane wave. The design problem is to select weights  $\omega_i$  that achieve a desired directional pattern  $G(\theta)$ . We now describe a basic weight design problem. We require unit gain in a target direction  $\theta^{tar}$ , i.e.,  $G(\theta^{tar}) = 1$ . We want  $G(\theta)$  small for  $|\theta - \theta^{tar}| \geq \Delta$ . This number is called the sidelobe level for the array; our goal is to minimize the sidelobe level. If we achieve a small sidelobe level, then the array is relatively insensitive to signals arriving from directions more than  $\Delta$  away from the target direction. This results in the optimization problem:

minimize 
$$\max_{|\theta-\theta^{tar}|\geq \Delta} |G(\theta)|$$
 subject to 
$$G(\theta^{tar})=1$$

with  $\omega \in \mathbb{C}^n$  as variables.

The objective function can be approximated by discretizing the angle of arrival with (say) N values (say, uniformly spaced)  $\theta_1, ..., \theta_n$  over an interval  $[-\pi, \pi]$ , and replacing the objective with

$$max\{G(\theta_k) \mid |\theta_k - \theta^{tar}| \ge \Delta\}$$

- (a) Formulate the antenna array weight design problem as an SOCP.
- (b) Solve an instance using CVX, with n=40,  $\theta^{tar}=15^{\circ}$ ,  $\Delta=15^{\circ}$ , N=400, and antenna positions generated using:

```
rand('state',0);

n = 40;

x = 30 * rand(n,1);

y = 30 * rand(n,1);
```

Compute the optimal weights and make a plot of  $|G(\theta)|$  (on a logarithmic scale) versus  $\theta$ . Hint. CVX can directly handle complex variables, and recognizes the modulus abs(x) of a complex number as a convex function of its real and imaginary parts, so you do not need to explicitly form the SOCP from part (a). Even more compactly, you can use norm(x, Inf) with complex argument.

Solution:

The problem can be expressed as the SOCP:

minimize 
$$t$$
 subject to 
$$||A_k x||_2 \le t, \ k \in \mathcal{I}$$
 
$$Bx = d$$

with variables  $x, t, \mathcal{I} = \{k | |\theta - \theta^{tar}| \geq \Delta\}$  and

$$x = \begin{bmatrix} \omega_{re} \\ \omega_{im} \end{bmatrix} \in R^{2n}$$

$$A_k = \begin{bmatrix} \cos(\gamma_1(\theta_k)) & \dots & \cos(\gamma_n(\theta_k)) & -\sin(\gamma_1(\theta_k)) & \dots & -\sin(\gamma_n(\theta_k)) \\ \cos(\gamma_1(\theta^{tar})) & \dots & \cos(\gamma_n(\theta^{tar})) & -\sin(\gamma_1(\theta^{tar})) & \dots & -\sin(\gamma_n(\theta^{tar})) \end{bmatrix}$$

$$B_k = \begin{bmatrix} cos(\gamma_1(\theta^{tar})) & \dots & cos(\gamma_n(\theta^{tar})) & -sin(\gamma_1(\theta^{tar})) & \dots & -sin(\gamma_n(\theta^{tar})) \\ sin(\gamma_1(\theta^{tar})) & \dots & sin(\gamma_n(\theta^{tar})) & cos(\gamma_1(\theta^{tar})) & \dots & cos(\gamma_n(\theta^{tar})) \end{bmatrix}$$

$$d = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

the matlab code:

```
clear all
rand('state',0);
%N= 10; %400;
%n = 2; %40;
N = 400;
n = 40;
x = 30 * rand(n,1);
y = 30 * rand(n,1);
X = [x'; y'];
beamwidth = 15*pi/180;
theta_tar=15*pi/180;
theta = linspace(theta_tar+beamwidth, 2*pi+theta_tar-beamwidth, N)';
A = \exp(i * [\cos(theta), \sin(theta)] * X);
Atar = exp(i * [cos(theta_tar), sin(theta_tar)] * X);
cvx_begin
variable w(n) complex
minimize(max(abs(A*w)))
subject to
Atar*w == 1;
cvx\_end
gamma = zeros(n, N);
for i = 1:n
for j = 1:N
gamma(i, j) = x(i) * cos(theta(j)) + y(i) * sin(theta(j));
end
end
```

```
size(gamma)

G = zeros(N, 1);

for i = 1:N
    for j = 1:n
    omega = w(j);
    rw = real(omega);
    iw = imag(omega);
    g = gamma(j, i);
    G(i) = G(i) + complex(rw * cos(g) - iw * sin(g), ...
    (rw * sin(g) + iw * cos(g)));
end
end

abs_G = abs(G)
```

Something wrong with this task here
